The present study incorporated plant derived compound to intervene the effect caused by SARS-CoV-2 protein using *in silico* techniques. *Luteolin* (Lut) is a significant flavonoid generated from plants that is found in a variety of edible herbs and vegetables possessing anti-inflammatory, anti-cancer, anti-oxidant, anti-apoptotic, and neurotrophic activities. In this study, the bioactivity of *Luteolin* derived from vegetable is studied using advanced Cheminformatics tools. Next, the SARS-CoV-2 protein sequence is retrieved and applied to an automated docking server in order to identify the molecular interaction between SARS-CoV-2 protein sequence and *Luteolin*. The results obtained from docking showed good affinity between *Luteolin* and SARS-CoV-2 protein sequence. All the results obtained were analyzed in 3D form using 3D visualization tools. In conclusion, the molecular dynamic studies clearly revealed that the identified compound *Luteolin* is a potential inhibitor for the selected target protein sequence of SARS-CoV-2.

***Key words*:** *Luteolin*, SARS-CoV-2, Swiss Similarity, HDOCK, Discovery studio

The World Health Organization (WHO) declared an unexpected pandemic outbreak of newly identified diseases, severe acute respiratory disease syndrome corona virus 2(SARS-CoV-2) in December 2019. SARSCoV-2 can cause serious side effects, such as septic shock and multiple organ failure, which can be fatal, especially in high-risk individuals, such as those that are immunocompromised and have underlying illnesses such malignancies, diabetes, cardiovascular disease, and chronic respiratory disorders [1]. The current COVID-19 outbreak was caused by the highly contagious SARS-CoV-2 bacterium, which has been linked to an unusually high number of infections and fatalities worldwide. The major problem confronting our global healthcare system is the paucity of therapeutic interventions for COVID-19 [2]. The SARS-CoV-2 spike (S) protein is made up of two subunits, S1 and S2, and is essential for receptor identification and cell membrane fusion. The host receptor Angiotensin-converting enzyme 2 (ACE2) is recognized and bound by the receptor-binding domain of the S1 subunit, while the two-heptad repeat domain of the S2 subunit facilitates the fusing of the viral cell membrane [3]. For viral entrance and subsequent replication, interactions between the SARS-CoV-2 receptor binding domain and the Angiotensin-converting enzyme 2 (ACE2) are essential. Finding a suitable small-molecule drug that can bind and disrupt regulatory processes has remained challenging due to the broad and featureless contact surfaces of both proteins [4]. Researchers have frequently concentrated on ways to interfere with the functional proteins on the virus's active binding site, the spike that binds to human cells, in the quest to develop viable treatments for SARS-CoV-2, the virus that causes COVID-19 [5].

The development of novel drug delivery technologies for the encapsulation of plant active metabolites, including organic, inorganic, and hybrid nanoparticles, has made remarkable progress over the past few decades [6]. There is always a need for new and innovative medicines. Despite improvements in synthetic chemistry, nature continues to be a valuable source for the development of new drugs [7]. *Luteolin* (Lut) is a significant flavonoid generated from plants that is found in a variety of edible herbs and vegetables. Studies using both human and animal models have demonstrated that *Lut* possesses a variety of pharmacological effects, including anti-inflammatory, anti-cancer, anti-oxidant, anti-apoptotic, and neurotrophic activities [8-9]. According to several studies, *Luteolin*'s protective properties are explained by its ability to prevent 2003-emerging SARS-CoV from entering human receptors and fusing with them. Therefore, regular consumption of foods that have a suitable quantity of *Lut* in our diets may be beneficial in preventing both the SARS-CoV-2 infection and the ensuing symptoms in COVID-19 patients [10]. Flavonoids and their derivatives may represent potential compounds to be investigated in upcoming clinical trials to bolster the

pharmacological library against corona virus infections owing to their pleiotropic effects and lack of systemic toxicity [11].

Our rate and possibility of discovering therapeutic metabolites have increased as a result of recent developments in bioinformatics and *in silico* screening [7]. Drug development can be conducted more efficient and low expense by using computational methods to discover compounds early on that exhibit both favourable and unwanted features. To better understand the molecular mechanisms of small compounds, computational techniques like molecular docking, molecular dynamics (MD), and enhanced sampling methodologies are frequently utilized in drug design, discovery, and development [12]. A complete understanding of drug release processes, material qualities, formulation/device factors, and their interactions with drug release profiles are necessary for designing improved drug delivery systems. Quantitatively achieving the objective goals is challenging without the proper computational tools. As a result, computational techniques for dosage form design have been created [13]. The present study included a range of computational tools owing to the benefits of computational methods in drug design.

MATERIALS AND METHODS

Ligand-based virtual screening

Virtual screening is one of the most used computer methods in pharmacological research. These web tools and databases enable computational professionals as well as wet-lab researchers to effectively incorporate a wide variety of data sources and cutting-edge drug design techniques into the routine research operations [14]. Using the Swiss Similarity web tool [15] the canonical SMILES of *Luteolin* molecule that were retrieved from NCBI PubChem (https://pubchem.ncbi.nlm.nih.gov/) were run for virtual similarity screening.

Molecular drug docking studies

HDOCK (http://hdock.phys.hust.edu.cn/) server was employed for docking *Luteolin* bioactive compound and Spike glycoprotein of SARS-CoV-2. The HDOCK server is a highly integrated set of tools for robust and quick protein-protein docking that includes homology search, template-based modelling, structure prediction, macromolecular docking, biological information incorporation, and task administration [16]. Several biological processes depend critically on interactions between proteins-proteins and DNA/RNA. It is useful to determine the intricate structures of these interactions, and molecular docking has been crucial in this process [17].

Visualization of the docked compound

After molecular drug docking studies of *Luteolin* bioactive compound and Spike glycoprotein of SARS-CoV-2, visualization of their 3D structure was done using Discovery Studio.

RESULTS AND DISCUSSION

An interface for ligand-based virtual screening of chemical libraries is provided by the online programme Swiss Similarity (http://www.swisssimilarity.ch), which enables users to look for compounds that are similar to a query molecule [18]. The fingerprinting technique chosen for the molecular representation, however, might have a substantial impact on the similarity values for a given set of compounds [18-19]. As seen in (Fig 4-6), the output of the query compound is shown with calculated similarity and scores. All similarity scores, which were determined using various methods, ranged from 0 for completely different compounds to 1 for identical ones. According to the similarity principle, the Swiss Similarity output list of molecules should be enriched in compounds that are anticipated to have comparable protein targets to the query molecule and can, as a result, be procured and experimentally examined first [19]. For simple visualization, output

compounds are displayed in the web browser along with their calculated similarity to the query compound [17]. Swiss Similarity provides many compound libraries for screening, including licensed drugs, identified bioactive molecules, readily available commercial compounds, and compounds that can be produced synthetically. Swiss Similarity offers a variety of 2D and 3D molecular fingerprints that encode compounds in various digital forms that may be used to calculate molecular similarity [20]. Molecular Drug docking studies for *Luteolin* bioactive compound and Spike glycoprotein of SARS-CoV-2 employing HDOCK server illustrating drug binding affinities of Ligand and Receptor as seen in (Fig 7) and the docked compound is viewed using Discovery Studio as seen in (Fig 8-10). Docking is a sampling and scoring process when two distinct structures are given, docking seeks to sample every potential binding mode between them. The sampled binding modes are then ranked during and/or after sampling using a scoring algorithm [17]. The results obtained clearly showed that the intramolecular electrostatic force is based on the binding affinity between the ligand-receptor complexes. (Table 1) clearly demonstrates the ligand and receptor interface amino acid residues which shows that the selected drug compound can act as an efficient inhibitor for the target corona virus protein.

CONCLUSION

A fatal corona virus (CoV) entered human society for the third time since the turn of the millennium, causing a global healthcare catastrophe that overwhelmed the system and had an impact on the globe economy. From this research investigation, we conclude that *Luteolin* efficiently inhibits SARS-CoV-2 protein. The results obtained from this study play a major role in the field of current viral informatics studies.
